

Leveraging Multi-CDN Strategies for Enhanced Performance and Monitoring

What is Multi-CDN Strategy?

Multi-CDN, or Multi-Content Delivery Network, is an approach that uses multiple CDN providers to deliver content to end users.

This strategy enhances performance, reliability, and global reach by leveraging the strengths of different CDN networks.

How It Works

Streaming Industry Breakdown

74% of video providers are already Multi-CDN or are planning to add additional CDNs in the near future.

32% up from 5 years ago.

Hybrid model of private CDN
with third-party CDN(s)

26%

Using multiple third-party CDNs

1 Enhanced Global Coverage

Strategically spreads across regions

-> Improved global latency

Navigates regional regulatory constraints

Allows granular control over content delivery

2 High Reliability

Reroutes traffic through another CDN if one is overwhelmed or down

-> 100% uptime guaranteed

3 Better User Experience

Ensures content delivery from best performing CDN with intelligent traffic distribution

-> Improved load times

4 Improved Security

Mitigates attacks by rerouting traffic to an unaffected CDN

-> Dual-layer protection enhancing performance and security

5 Cost Saving

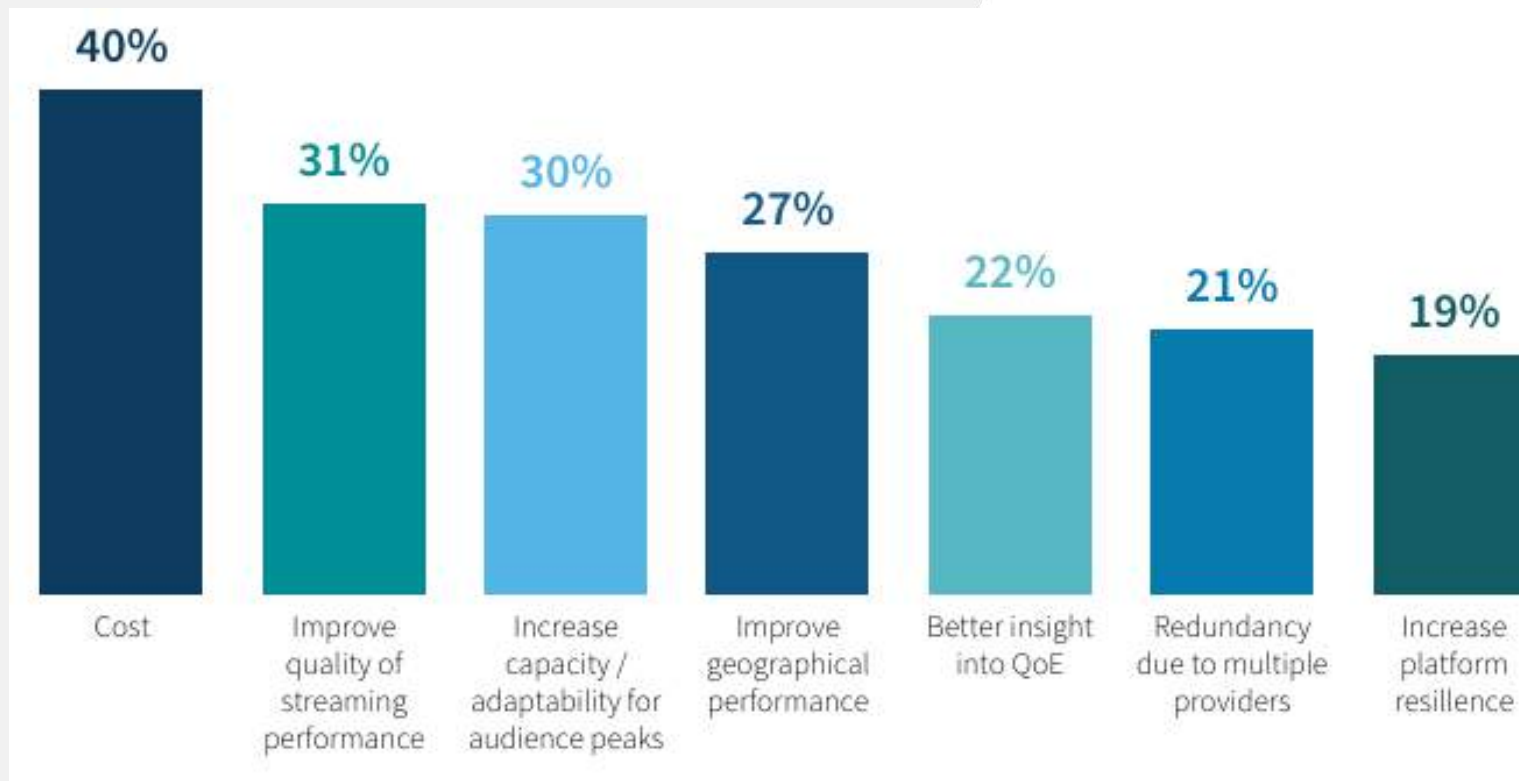

CDN providers have varying pricing based on regions, peak hours and traffic volumes.

-> Avoids overage fees and optimize bandwidth costs

6 Service Customization

Allows to adopt different CDNs for image optimization, content delivery and security based on performance.

Main reasons to choose the Multi-CDN approach for video delivery;

Evolution of Total Broadband Data Traffic in Turkey

Evolution of Total Broadband Data Traffic in KSA and UAE

Monitoring & Observability Challenges

Lack of Integration Between CDNs and Media Players

Disconnected Data

Separate CDN data and player data result in a fragmented view of content delivery performance.

Reduced Observability

Overall observability diminishes, making it harder to monitor performance and granular details.

Troubleshooting Difficulties

The inability to correlate the performance metrics of CDN and player makes pinpointing issues challenging.

Lack of Integration Between CDNs and Media Players

- **Limited Insights:** Customers lack understanding of where issues are occurring - whether in the CDN delivery process or within the player's operation.

- **Increased Troubleshooting Time:** The lack of integrated data means more time and effort needed to identify and resolve issues as teams must manually correlate data.

- **Suboptimal Performance:** Without synchronized data, optimizing content delivery for better performance becomes challenging. This leads to higher buffering rates and slower start times.

Data Synchronization

New ETL Processes

CDN logs and player logs can be pushed into a common platform through an API.

Pro: easy to implement | Con: non-real-time and possibly lacking critical details

New Data Pipelines

Robust data pipelines can be established for seamless, real-time data flow between CDNs and players.

Pro: real-time and in-depth insights | Con: very complex & costly to implement

Combining CDN and player data into a **single dashboard** with side-by-side charts enables real-time comparison and provides a holistic view of performance.

Developing **correlated metrics** that link CDN performance with player performance offers deeper insights into potential issues.

Enhanced Observability

Integrated Alert Mechanisms

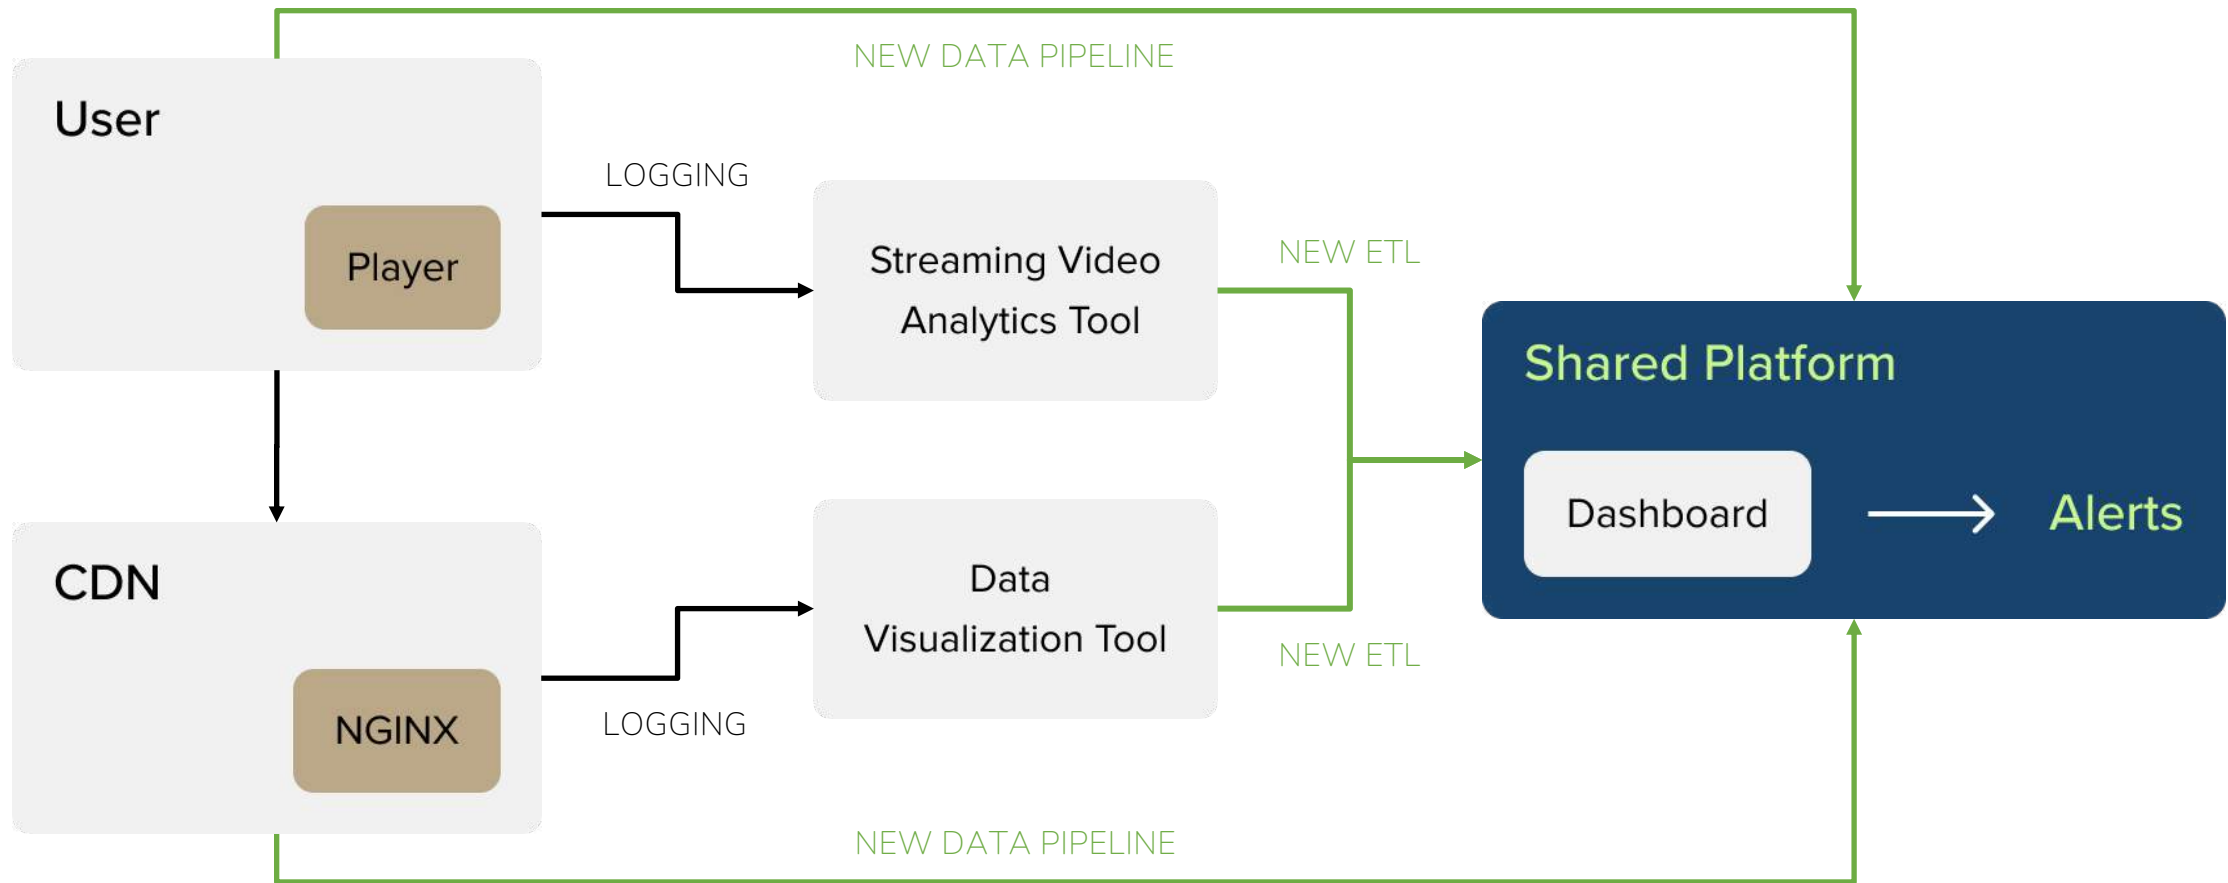

Real-time alerts trigger when performance metrics fall below predefined thresholds. This enables to proactively manage and solve issues.

Contextual alerts provide information that combines CDN and player data to accurately pinpoint the source of issues.
